ABSTRACT: [Part 1 of this series was published Ibid., Vol 15, 1965, pp 289-312] This instalment discusses operational effectiveness under conditions of occupancy and status of operational reserve under various operational conditions. The considerations presented were applied to calculations pertaining to a street crossing involving a main road and a secondary road, for cases in which the main road had one-way traffic, the main road had two-way traffic, and where various vehicle turning modes were permitted or prohibited. Equations were derived to assist in calculating the various traffic parameters involved. Orig. art. has: 26 formulas.

Effect of heating in the atmosphere of various gases on the plasticity of bituminous coals. Michał Choraży and Kazimierz Tomków. *Biul. Inst. Nauk.-Badawczego Przemysłu Węglowego (Katowice), Komun.* No. 31, 20 pp. (1948).—Samples of 7 Polish coals were heated for 30–45 min. at 100–180° in the atm. of air, N, NH<sub>3</sub>, CO<sub>2</sub>, steam, or SO<sub>2</sub>, after which their plasticity range was detd. by the Gieseler method (C.A. 28, 4567<sup>9</sup>). The plasticity curves of oxidized samples are generally lower than those of unoxidized samples, but the changes in the curves and the max. are irregular and cannot be used as a basis for classifying the coals with respect to coking properties. The effect of N, NH<sub>3</sub>, and CO<sub>2</sub> is slight, but that of steam is appreciable, particularly at temps. close to the beginning of the plasticity range. The oxidizing effect of SO<sub>2</sub> is greater than that of air. Bruno C. Metzger.

AUTHOR: Tomková, E.

TITLE: Direct conversion of thermal energy into electrical energy by means of thermoemission

PERIODICAL: Československý časopis pro fysiku //no.6, 1961, 516-534

TEXT: This paper is a review of published work on this subject and contains 21 references.

The main obstacle to the efficient operation of a diode for the direct conversion of thermal energy into electrical power is the formation of a space charge which causes a minimum of potential in the space between cathode and collector. K.G. Hernquist (Ref.1: K.G. Hernquist, M. Kanefsky, F.H. Norman, RCA Rev., Vol.19, (1958), 244) lists a number of methods for the removal of this minimum. H. Moss (Ref.2: Journ. Electronics, Vol.2(1957), 305) has derived a theory of such diodes operating without a potential minimum because of the close proximity of cathode and collector. According to Moss, the largest possible power output per unit area of the cathode is:

Card 1/7

Direct conversion of thermal energy...

30598  
Z/037/61/000/006/004/004  
E024/E135

$$P_{\max} = I_s (kT/e) \quad (18)$$

where;  $I_s$  is the saturated collector current density;  $R$  is the external load resistance (the internal resistance of the diode is neglected); the other symbols have their usual meaning.  $I_s$  is obtained when the potential difference between cathode and collector is zero. H.F. Webster (Ref.8; J. Appl. Phys. Vol.30, (1959), 488) derived the maximum power for the case when the potential minimum cannot be neglected. In this case we obtain:

$$P_{\max} = \frac{I_s \cdot k \cdot T \cdot a}{e} \quad (25)$$

The value of the parameter  $a$  is obtained from Fig.5, where  $a$  is plotted as a function of  $(e/kT)(\phi_c - \phi_K)$  for various parameters  $K$ .  $\phi_c$  is the work function of the collector,  $\phi_K$  the work function of the cathode, and

EO24/E135

$$K = 84.24 \cdot 10^{10} \frac{I_s \cdot s^2}{T^{\frac{3}{2}}} \quad (24)$$

where  $s$  is the distance from collector to cathode. The efficiency of diodes as converters of thermal energy into electrical energy has been discussed by N.D. Morgulis and P. Marčuk (Ref.11: Ukrainskiy fizichesniy zhurnal, Vol.2 (1957), 379) and by J.M. Houston (Ref.12: J. Appl. Phys., Vol.30 (1959) 481). The theoretical efficiency is given by:

$$\eta = \frac{I_c (V_K - V_c - V_v)}{q_r + q_c + I_c \left( V_K + \frac{2kT}{e} \right)} \quad (36)$$

where:  $q_r$  are the radiative heat losses;  $q_c$  are the heat losses due to conduction in the leads;  $I_c$  is the collector current;  $V_K = \varphi_K + V_m$ ;  $V_c = \varphi_c + \delta$ ;  $V_m$  is the minimum potential in the space charge, measured from the cathode;  $\delta$  is the potential difference between the collector and the minimum potential;

Card 3/7

30598

Direct conversion of thermal energy ... E024/E135

$V_v$  is the voltage developed on the leads. Fig. 8 shows  $\eta$  as a function of the temperature of the cathode ( $T$ ) for various densities of emission current and for  $V_c = 1$  Volt. Experimentally, P.M. Marčuk (Ref. 13; Trudy instituta fiziki 1956, 3) has used a method of neutralising the space charge by positive Cs ions. The ions are formed by thermal ionization on the cathode and the Cs vapour serves the double purpose of neutralizing the space charge and reducing the work function of the collector. The conversion efficiency achieved in this experiment was 0.7% with a cathode temperature of 2400 °K. A similar arrangement was used by K.G. Hernquist et al. (Ref. 1). These authors obtained the dependence of the collector current  $I_c$  upon the voltage developed on the external resistance,  $I_c R$  (Fig. 10). The contact potential difference between cathode and collector was 2.7 Volt. The maximum efficiency was 10.4% at  $T = 2910$  °K. V.C. Wilson (Ref. 15; J. Appl. Phys., Vol. 30 (1959) 475) used a similar system but, instead of relying on the ionization of the caesium on the cathode, he used a separate source of ions. This led to improved efficiency of the diode, but only when the consumption of the ion

Card 4/7

30598

Direct conversion of thermal energy ... Z/037/61/000/006/004/004  
EU24/E135

source was not taken into consideration. G.N. Hatsopoulos and J. Kaye (Ref.4: J. Appl. Phys., V.29 (1958) 1124) used the method of close proximity of cathode and collector to avoid an undesirable space charge. They chose the distance  $s = 0.025$  mm and used an indirectly heated molybdenum cathode and an identical collector. With  $T_k = 1538$  °K and  $T_c = 811$  °K they claimed an efficiency of almost 13% but, according to Ref.16 (a later paper) it was really only 10.7%. All the above mentioned experimental diodes used electric heating for the cathodes, i.e. converted electrical energy into electrical energy. G.M. Grover (Ref.17: Nucleonics Vol.17 (1959), 54) used the energy released in the fission of enriched uranium in the cathode when this was irradiated by neutrons in a reactor. He estimated the efficiency of his diode at 5% with an output of 30 Watt. The author concludes that, in spite of the present low efficiencies, the system might have future practical applications. There are 12 figures, 1 table and 21 references: 6 Soviet-bloc and 15 non-Soviet-bloc. The most recent English language references read as follows:

TITLE: Influence of ultraviolet radiation on a thermionic converter

SOURCE: Chekhoslovatskiy fizicheskiy zhurnal, v. 15, no. 7, 1965, 526-528

TOPIC TAGS: UV irradiation, thermoelectric converter, cesium, temperature dependence, pressure effect, space charge

ABSTRACT: The purpose of the investigation was to obtain a source of positive ions to cancel out the space charge of the electrons in a thermionic energy converter operating with a low-temperature cathode (near 1000C). The authors describe tests in which the ions were provided by cesium vapor exposed to ultraviolet radiation. The experimental setup is shown in Fig. 1 of the Enclosure. The system was kept in a vacuum of  $10^{-6}$  mm Hg, and the vapor pressure of the cesium could be controlled by varying the temperature of the furnace in which the entire assembly was kept. The results showed that the converter produces a maximum current at a cathode temperature below 1000C, and that an increase in the temperature leads to a decrease in the current. The reason for it is that the number of ions produced by photo ionization of the cesium is effective only up to a certain current density. At

Card 1/3

L 8190-66

ACCESSION NR: AP5018473

higher temperature of the cathode (at higher termionic emission density) the space charge of the ions becomes negligible compared with the space charge of the electrons and its influence diminishes. Further tests with more intense ultraviolet light are planned. Orig. art. has: 3 figures. 5544

3759. INFLUENCE OF VARIOUS FACTORS UPON YIELD OF BY-PRODUCTS IN LABORATORY CARBONIZATION OF COAL AT HIGH AND LOW TEMPERATURES. Tsekow, K. (Katonica: Prace Inst. Gór. (Res. Proc. Chief Inst. Min.), 1950, Katedra CC, 12pp.). The influence of various factors on the yield of by-products in laboratory carbonization of coal was investigated:- 1. Cracking temperature. 2. The various fillings of the cracking space. 3. Time of carbonization. 4. The effect of coal gas, hydrogen and nitrogen feed on the coal charge and the cracking space. 5. The effect of superheated steam fed into the coal charge. It is shown that an essential factor influencing the yield and the quality of carbonization of by-products is the temperature of the cracking space. The yield of benzol increased, by 27.6%, when the coal gas was fed into the coal charge during carbonization. The effect of superheated steam is chiefly to increase the tar and ammonia yield. Tar recovered under these conditions is like low temperature carbonization tar. The effect of the other above mentioned factors proved insignificant. (L).

Catalytic hydrogenation of D-xylose by using Raney-nickel catalyst. Desider Tomkujak (Slovak Tech. Univ., Bratislava, Czech.). *Chem. Zvesti* 3, 229-24 (1949). D-Xylose was hydrogenated according to French 891,421 (C.A. 25, 1840) at 30° and 1 atm. in a 10% aq. soln. and in 50% MeOH, and the reaction rate const. measured. If D-xylose is hydrogenated in H<sub>2</sub>O with 30% of Raney Ni, D-xylonic acid produced by the Cannizzaro reaction decreases the pH of the soln. and the activity of the catalyst. The reaction rate decreases continuously and the hydrogenation lasts 3-4 days. When the amt. of catalyst is increased from 3 to 30%, the Ca(OH)<sub>2</sub> from 0.5 to 1.5% (based on xylose), and the solvent 4 times, the pH of the soln. and the activity of the catalyst are not changed, and the reaction rate is kept const. Hydrogenation at 30° and 1 atm. lasts about 24 hrs. By increasing the temp. up to 70°, the reaction time is decreased to 7-8 hrs., and 90% of the theoretical amt. of xylitol free of Ni, by a 230-30%, is formed. Jan Micka

Acetone derivatives of xylitol and their constitution.  
František Valentin and Dezider Tomkuljak (Slovak Tech.  
Univ., Bratislava, Czech.). *Chem. Zvesti* 3, 146-64 (1949).  
—Diacetonexylitol was prepd. and its constitution detd.  
On treatment with  $\text{Me}_2\text{CO}$  and concd.  $\text{H}_2\text{SO}_4$ , xylitol (I)  
binds first 1 mol. of  $\text{Me}_2\text{CO}$  in a 6-membered heterocycle  
at positions 3 and 5 of the I mol., forming the amorphous  
monaacetonexylitol,  $b.p.$  145-7°,  $n_D^{20}$  1.4778. Prolonging  
the reaction time and increasing the amt. of the condensa-  
tion agent gives diacetonexylitol, in which the 2nd mol. of  
 $\text{Me}_2\text{C}$  is bound at positions 1 and 2 of the sugar mol.,  
forming a 5-membered heterocycle; the amorphous 1,2,-  
3,5-diacetonexylitol  $b.p.$  99-101°,  $n_D^{20}$  1.4534. The follow-  
ing derivs. of I were prepd. by oxidation with  $\text{Pb}(\text{OAc})_2$ :  
1,2,3,5-diacetone-4-tolylsulfonyl, *cryst.*, *m.* 71-3°; 3,5-  
acetone-1,2,4-tribenzoyl, *cryst.*, *m.* 103-4°; 3,5-acetone-  
1,2,4-trimethyl, amorphous,  $b.p.$  69-71°,  $n_D^{20}$  1.4324;  
1,2,4-trimethyl, amorphous,  $b.p.$  97-9°,  $n_D^{20}$  1.4510;  
1,2,3,5-diacetone-4-methyl, amorphous,  $b.p.$  78-80°,  
 $n_D^{20}$  1.4393; 3,5-acetone-4-methyl, amorphous,  $b.p.$  109-  
11°,  $n_D^{20}$  1.4003; 4-methyl, amorphous,  $b.p.$  167-9°; 1,2,-  
3,5-tetrazobenzoyl-4-methyl, *cryst.*, *m.* 121-3°.

TIME: Multipurpose relaxation apparatus for measuring the signs of elementary pro-  
cesses in ionic crystals subjected to ionizing radiation

SOURCE: AN LatSSR. Izvestiya. Seriya fizicheskikh i tekhnicheskikh nauk, no. 6,  
1965, 11-18

TOPIC TAGS: relaxation process, ionizing radiation, ionic crystal, electron emission,  
luminescence, photoluminescence

ABSTRACT: The authors point out that all the previously developed multipurpose in-  
stallations ("relaxation combines") designed for the investigation of relaxation  
(transient) processes in ionic crystals exposed to ionizing radiation suffer from an  
important shortcoming in that they do not make it possible to determine one of the  
most important characteristics of the relaxation process, namely, its sign, in spite  
of the fact that the mechanism of the relaxation process depends essentially on whether the  
relaxation process is electronic or of the hole-type. The authors therefore describe  
apparatus in which the sign of the elementary process is determined by means of  
thermally stimulated electron emission. An earlier version of the apparatus was al-  
ready described (Tr. IFA AN ESSR, 1960, 12, 241). The apparatus is a combination of

Card 1/2

ACC NR: AF0016814

a spectrophotometer (SF-2M) and devices that produce and register luminescence and thermally stimulated electron emission. It permits simultaneous measurement of thermally stimulated luminescence, thermal discoloring, thermo-optical de-excitation, and thermally stimulated as well as photostimulated electron emission. Simultaneous measurement of absorption, luminescence, and electron emission can also be made while the sample is heated at a constant rate. The individual parts of the apparatus are described and results of measurements of NaCl(Tl) exposed to x rays are presented by way of an example. A detailed discussion of the results will be published in a separate article. The authors are grateful to Ch. B. Lushchik for suggesting the topic. Orig. art. has: 5 figures.

TITLE: On the question of the background of nuclear emulsions used in the study of  $\alpha$ -radioactivity in the atmosphere

SOURCE: Akademiya nauk Litovskoy SSR. Trudy. Seriya B. no. 1, 1963, 29-32

TEXT: In connection with the study of radioactivity in the atmosphere, the authors investigate the background of nuclear emulsions of the A-2 type of thickness  $50\ \mu$ , since the presence of this background may have a considerable effect on experimental results at low frequency levels. The  $\alpha$ -tracks were observed with an MSN-2 (MBI-2) microscope, with magnification  $\times$  (675 - 1350). Testing of different nuclear emulsions showed that the general background increases daily by about  $10\ \alpha$ -tracks/cm<sup>2</sup>, but in the upper layer ( $10\ \mu$ ) of the emulsion by only  $0.5\ \alpha$ -tracks/cm<sup>2</sup>. The increase of background with depth may indicate the presence of radio-atoms in the glass base or a contaminated under-layer. The

reduction in the number of tracks in the upper layer may also indicate that the regression of  $\alpha$ -tracks proceeds more effectively when in direct contact with air. It is recommended that for the study of the radioactivity of the atmosphere the contact method of irradiating the emulsion should be used since in this case the majority of the  $\alpha$ -tracks are situated in the surface layer, and in order to take into account the background according to the separate components in this layer. The composition by components as also the total background were studied using  $H_2O$  and  $H_2O_2$  vapor, in a solution of  $K_3Fe(CN)_6$ , and in an atmosphere of oxygen. The use of  $H_2O_2$  vapor and of a 1%  $K_3Fe(CN)_6$  solution proved most effective, tests being made at 5-minute intervals in the latter case. The results of testing are presented in the form of a histogram, which takes the general form of a Poisson distribution with mode at  $24 \mu$ , but having a subsidiary peak at  $40 \mu$ . There are 1 figure and 3 tables.

Voprosy obrabotki metallov davleniyem (Problems of Metal Forming) Moscow, Izd-vo AN SSSR, 1958. 85 p. 4,500 copies printed.

Resp. Ed.: Tselikov, A.I., Corresponding Member, USSR Academy of Sciences;  
Ed. of Publishing House: Bankvitser, A.L.; Tech. Ed.: Guseva, I.N.

PURPOSE: This book is intended for scientific research workers and designers in the field of metal forming.

COVERAGE: This book contains 4 articles which discuss various theoretical aspects of metal forming, such as the theory of sheet-metal forming (drawing), the experimental design of complex drawing dies, and data on research work for determining the actual magnitude and character of forces in rolling of metals to achieve maximum utilization of power and reduction of weight of existing rolling equipment and of new machinery under construction.

TITLE: The Plastic State of Stress and the Stability of the Process of Drawing of Complex Shapes (Plasticheskoye narpyazhennoye sostoyaniye i ustoychivost' protsessa vytyazhki detaley slozhnoy formy)

PERIODICAL: V sb.: Vopr. obrabotki metallov davleniyem. Moscow, AN SSSR, 1958, pp 3-23

ABSTRACT: During die stamping of components having the shape of complex shells, the area of the blank immediately underneath the blank hold-down ring is small in comparison with its total area. In the process of stamping, the entire area of the blank undergoes plastic deformation. The flanges of drawn articles are not flat and the stresses which exist in them are not axially symmetrical. By applying methods of the internal geometry of surfaces to an analysis of stresses arising in articles of complex shape, a natural extension of the theory of slip lines is obtained in a generalized form for the case of three-dimensional shapes. The stress analysis is conducted in the right orthogonal system of curvilinear coordinates. It was established, in

Card 1/2

The Plastic State of Stress and the Stability of the Process (cont.) SOV/137-59-3-6876

the course of an analysis of the stability of the drawing process, that the plasticity of the metal is enhanced in the process of drawing. The effect of friction is evaluated with the aid of the Euler formula which acquires a somewhat modified form in the case of biaxial displacement of metal. The biaxial state of stress, which arises in the process of drawing of complex shapes, is a desirable condition which enhances the plasticity of the metal and is attributable to the greater stability of the process. Strain hardening of metal in the process of biaxial elongation favors large plastic deformations during stamping operations.  $\sigma_b$  and  $\delta$  values in simple tension are the most important characteristics of sheet metal governing its suitability for drawing.

	PURPOSE: This collection of articles is intended for specialists in the petroleum and gas industry. It will also be of interest to scientific research institutions, teachers and students of vuses.	
	COVERAGE: This collection of articles reviews problems connected with natural and synthetic gas production. A number of articles are devoted to the study of regional oil- and gas-bearing zones, the crystalline beds underlying the Volga-Ural petroleumiferous regions, the techniques of the Caspian depression, seismic prospecting, oil well logging, development of oil and gas fields, petroleum-bearing formations and their physical characteristics, and petroleum engineering. Other articles deal with the production of heavy- petroleum compounds, the application of fine exchange ions, catalytic methanolization, continuous coking of heavy petroleum residues, (fluidi- zation), the improvement of lubricating oil and greases. The book contains with tables on properties of lubricating oil and greases. The book contains numerous photographs, tables, flow sheets, and diagrams, among which those relating to coal gasification and processing of heavy petroleum resi- dues over a fluidized catalyst deserve special attention. References accompany individual articles.

Reep. M.: D. B. Reebster, Professor, Doctor of Technical Sciences;  
M.: of Publishing House: G. B. Gurebikov; Tech. M.: G. T. Zubin.  
PURPOSE: This book is intended for engineers and scientists concerned with  
the problems of the strength of materials and construction.

COVERAGE: The book contains 30 articles on the strength of materials in  
general and of machine construction in particular. This collection  
was prepared under the direction of the Institute of Mechanical Engineering  
of the Academy of Sciences of the USSR. It is a part of a series of books  
devoted to the problems of the strength of materials. The first part  
contains 30 articles on the strength of materials. The second part  
contains 30 articles on the strength of machine construction materials.  
The third part contains 30 articles on the strength of machine construction  
materials. The fourth part contains 30 articles on the strength of machine  
construction materials. The fifth part contains 30 articles on the strength  
of machine construction materials. The sixth part contains 30 articles on  
the strength of machine construction materials. The seventh part contains  
30 articles on the strength of machine construction materials. The eighth  
part contains 30 articles on the strength of machine construction materials.  
The ninth part contains 30 articles on the strength of machine construction  
materials. The tenth part contains 30 articles on the strength of machine  
construction materials. The eleventh part contains 30 articles on the  
strength of machine construction materials. The twelfth part contains 30  
articles on the strength of machine construction materials. The thirteenth  
part contains 30 articles on the strength of machine construction materials.  
The fourteenth part contains 30 articles on the strength of machine  
construction materials. The fifteenth part contains 30 articles on the  
strength of machine construction materials. The sixteenth part contains 30  
articles on the strength of machine construction materials. The seventeenth  
part contains 30 articles on the strength of machine construction materials.  
The eighteenth part contains 30 articles on the strength of machine  
construction materials. The nineteenth part contains 30 articles on the  
strength of machine construction materials. The twentieth part contains 30  
articles on the strength of machine construction materials. The twenty-first  
part contains 30 articles on the strength of machine construction materials.  
The twenty-second part contains 30 articles on the strength of machine  
construction materials. The twenty-third part contains 30 articles on the  
strength of machine construction materials. The twenty-fourth part contains  
30 articles on the strength of machine construction materials. The twenty-  
fifth part contains 30 articles on the strength of machine construction  
materials. The twenty-sixth part contains 30 articles on the strength of  
machine construction materials. The twenty-seventh part contains 30  
articles on the strength of machine construction materials. The twenty-  
eighth part contains 30 articles on the strength of machine construction

Osnovy teorii obrabotki metallov davleniyem (Fundamentals of the Theory of Metal Forming) Moscow, Mashgiz, 1959. 538 p. Errata slip inserted. 7,500 copies printed.

Ed.: M. V. Storozhev; Ed. of Publishing House: A. I. Sirotin, Engineer; Tech. Ed.: B. I. Model'; Managing Ed. for Literature on Heavy Machine Building (Mashgiz): S. Ya. Golovin, Engineer.

PURPOSE: This book is intended for engineers and scientific workers studying the theoretical problems of metal forming.

COVERAGE: This collective work purportedly reflects the contemporary trends in the development of the metal-forming theory. Emphasis is given to methods of calculating forces and deformations. The use of these methods is illustrated in analysis of smith- and drop-forging operations. No personalities are mentioned. There are 227 references: 197 Soviet, 17 German, and 13 English.

AUTHOR: Tomlenov, A.D., Doctor of Technical Sciences, Professor

TITLE: Features of Calculating the Stressed State Caused by Forging Between Flat Dies (Ob osobennostyakh rascheta napryazhennogo sostoyaniya, vznikayushchego pri kovke ploskimi boykami)

PERIODICAL: Vestnik Mashinostroyeniya, 1959, Nr 3, pp 46-47 (USSR)

ABSTRACT: D.K. Chernov (1867) and James Nasmyth (1885) are both said to have pointed out that round axle shafts, when forged between flat dies or strikers, are subject to internal tensile forces causing cracks, and that this can be prevented if the axles are forged between shaped dies. The stressed state occurring at points on a shaft compressed between flat dies (Fig 1) is calculated from Mises-Henckey integrals and the principal stress is found by use of Mohr circles in terms of specific pressure,  $p$ , to be given by Eq (7). The value  $p_{max}$  is found by using Prandtl's formula (Ref 4); it is given by Eq (14). Using Eqs (7) and (14) the maximum tensile stresses arising in the central section of the blank can be calculated. A table on p 47 gives the magnitude of the stresses in relation to the specific pressure on the dies

Card 1/2

SOV/122-59-3-14/42

Features of Calculating the Stressed State Caused by Forging Between Flat Dies

for different ratios of shaft diameter to width of die. Fig 3 shows the stress profile through the shaft when this ratio is 8.15. The tensile stress at the centre is considerable and may give rise to axial or transverse cracks if the metal is insufficiently plastic, or at too low a temperature during forging. The use of insufficiently powerful forging presses and too narrow dies can lead to transverse cracks. The proper solution, as pointed out by Chernov and Nasmyth, is to use shaped dies. There are 3 figures, 1 table and 7 references, 3 of which are Soviet, 2 German and 2 English.

TITLE: Plastic Bi-Axial Tensile Strength ✓

PERIODICAL: Tr. Mosk. in-t neftekhim. i gaz. prom-sti, 1959, No. 2<sup>4</sup>, pp. 170-173

TEXT: The author analyzes losses of strength of the second order occurring at a moment corresponding to maximum tensile forces. This is caused by the insufficient compensation of the stress increase due to a decrease in the modulus of metal strengthening, diminishing with greater deformation. On the basis of calculations presented, it is shown that the critical value of changes in the metal thickness during bi-axial stretching is 4 times higher than in uni-axial stretching. ✓

AUTHOR: Tomlenov, A. D., Doctor of Technical Sciences, Professor

TITLE: Penetration of rounded punch into metal with friction

PERIODICAL: Vestnik mashinostroyeniya, no. 1, 1960, 56-58

TEXT: The article presents an analysis of the case of a rounded punch and metal of ideal plasticity. The problem of the penetration of curved-outline punch in different friction conditions had been solved previously by V. V. Sokolovskiy [Ref. 1: Teoriya plastichnosti (Theory of plasticity), Gostekhizdat, 1950], and the problem of the penetration of a rounded punch in the absence of friction on the surfaces and of deformations in directions at right angles to the meridian punch sections by the author [Ref. 2: Teoriya plasticheskikh deformatsii (Theory of plastic strain), Mashgiz, 1951]. The slip band network had been constructed graphically by L. Prandtl (Ref. 3: Anwendungsbeispiel zu einem Henkischen Satz ueber Plastisches Gleichgewicht, ZAMM, Bd. 3, no. 6, 1923). The contact friction is assumed proportional to the yield limit, and the stress pattern considered to be two-dimensional. The closed solution obtained includes a slip band equation and formulae for calculation of stresses and forces. The

Card 1/5

Penetration of rounded punch ...

S/122/60/000/001/012/018  
A161/A130

slip bands network is shown in a figure. The tangential stresses on the contact surface ( $\tau_k$ ) are determined by the friction factor value

$$|\tau_k| = \mu 2K \quad (1)$$

where  $\mu$  is the mean friction factor value;  $K$  - the plasticity constant. The  $\alpha$  angle composed by the straight slip band lines with the tangent to the outline is determined by the friction factor:

$$2\alpha = \arccos 2\mu. \quad (2)$$

The slip band field is determined by the boundary conditions. In the abc area the grid consists of straight lines; in the acn area the lines form a centered fan, and in the eifan area they make a noncentered fan. The radius-vector of any h point of the curved slip band is

$$\vec{\rho} = r\vec{e}(\psi) - \lambda \frac{d}{d\psi} \vec{e}(\psi + \alpha) = r\vec{g}(\psi) - \lambda \vec{g}(\psi + \alpha) \quad (3)$$

where  $r$  is the punch end radius;  $\psi$  - angle between the radius of and the axis  $x$ ;  $\vec{e}(\psi)$  and  $\vec{g}(\psi)$  - circular vector functions being determined as unit vectors forming the angles  $\psi$  and  $\psi + \frac{\pi}{2}$  with the axis  $ox$ ;  $\lambda$  - a parameter equalling the fn length in absolute value. The  $\lambda$  is eliminated in further derivation of the vector equation of slip bands;

Card 2/5

Penetration of rounded punch ...

S/122/60/000/001/012/018  
A161/A130

$$\bar{\rho} = r [e(\psi) - (\psi - \psi_1) \cos \alpha \bar{g}(\psi + \alpha)], \quad (7)$$

or, in scalar form considering the relation (2):

$$\rho^2 = r^2 [1 - (\psi - \psi_1) \sqrt{1 - 4\mu^2} + (\psi - \psi_1)^2 (0.5 + \mu)]. \quad (8)$$

The mkle area presents the area of plastic equilibrium moving with the punch as a rigid body. Its boundaries (the ie and me lines) are the rupture lines for speeds. Considerable deformations appear in a thin metal layer along these lines, and the result may be local workhardening and lamination of metal along the plastic equilibrium area boundary. The boundaries of this area are determined by the condition that the slip bands ei and em cross the punch axis at a  $\frac{\tilde{\mu}}{4}$  angle, and

$$\psi_0 = \frac{\tilde{\mu}}{4} - \alpha. \quad (9)$$

At  $\alpha = 0$  the friction factor is highest ( $\mu = 0.5$ ), and limited by the plasticity. The slip bands are the involutes of the punch outline in this case, and the mean normal stress values and the turn angles of the tangents are bound by the Henky integral. For the ft slip band this integral is

$$\bar{\sigma}_f - \bar{\sigma}_t = -2K\varphi, \quad (11)$$

Card 3/5

Penetration of rounded punch ...

S/122/60/000/001/012/018  
A161/A130

"APPROVED FOR RELEASE: 04/03/2001" CIA-RDP86-00513R001756220010-7"

where  $\bar{\sigma}_f$  and  $\bar{\sigma}_t$  are normal stresses in the f and t points, and  $\varphi$  - the turn angle of the tangent of the slip band in the ft length. The  $\bar{\sigma}_f$  and  $\bar{\sigma}_t$  values are found by constructing the Mor's circles for the f and t points:

$$\bar{\sigma}_f = \bar{\sigma}_n + K \sin 2\alpha, \quad (12)$$

where  $\varphi_n$  is stress directed at right angles to the punch outline, and

$$\bar{\sigma}_t = -K. \quad (13)$$

The is found from the figure:

$$\varphi = \frac{3\tilde{\mu}}{4} - \psi - \alpha. \quad (14)$$

The values found in (12) and (13) are substituted into the equation (11), and is found as

$$\bar{\sigma}_n = -2K(\theta - \psi), \quad (15)$$

where

$$\theta = \frac{3\tilde{\mu}}{4} - \frac{\arccos 2\mu}{2} + \frac{\sqrt{1 - 4\mu^2}}{2} + 0.5 \quad (16).$$

For a particular case without friction (2),  $\mu = 0$ , and consequently

$$\bar{\sigma}_n = -2K(1 + \frac{\tilde{\mu}}{2} - \psi) \quad (17)$$

Card 4/5

Penetration of rounded punch ...

S/122/60/000/001/012/018  
A161/A130

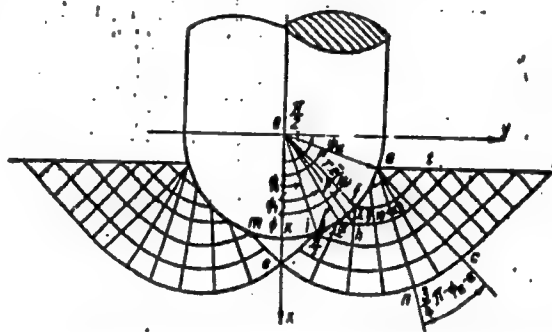

The specific pressure value related to the cross section area of the punch is determined by the integral from the normal and tangential stress components, taken on the contact surface:

$$\frac{p}{2K} = \frac{\sin^2 \psi_0}{2} + (\theta - \psi_\alpha) \sin^2 \psi_\alpha + \frac{[(2\psi_\alpha - \sin 2\psi_\alpha) - (2\psi_0 - \sin 2\psi_0)] (1 + \cos 2\alpha)}{4} \quad (18)$$

and in particular case without contact friction (Ref. 2), formula (18) becomes

$$\frac{p}{2K} = (1 + \frac{\pi}{2} - \psi_\alpha) \sin^2 \psi_\alpha + \frac{2\psi_\alpha - \sin 2\psi_\alpha}{4} \quad (19)$$

There are: 1 figure and 3 references;

TITLE: Theory of Testing Sheet Metal at High Deformation Speeds

PERIODICAL: Kuznechno-shtampovochnoye proizvodstvo, 1960, No. 7, pp. 5 - 6

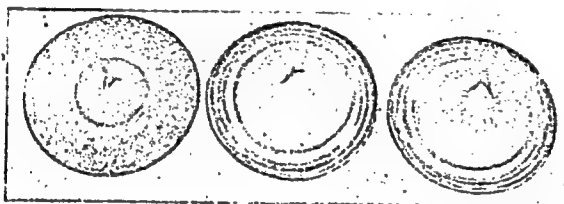

TEXT: The Laboratoriya obrabotki metallov davleniyem (the Laboratory of Metalworking by Pressure) of IMASH AN SSSR (the IMASH of the AS of the USSR) has developed a new method for testing sheet steel and its suitability for deformation by stamping. The method principle for metal testing consists of a hydraulic stroke with biaxial drawing and has been granted the Author's Certificate No. 115711 (Ref. 4) in 1958. Round sheet specimens used in this test are shown in a photo. The theory of the method is explained. It includes the use of known formulae (Korteweg, Bernoulli) of shock wave propagation. The mean total stroke pressure  $p_m$  is calculated by the formula 
$$p_m = \frac{GH\eta}{q}$$
 where  $q$  is the volume

fluid displaced by the stroke;  $G$  - the weight of falling parts of the test instrument;  $H$  - the height of the drop; and  $\eta$  - the stroke efficiency (calculated by formula (24)). Knowledge of the summary pressure in the instrument ( $p_s$ ), the

Card 1/2

Theory of Testing Sheet Metal at High Deformation Speeds S/182/60/000/007/002/016  
A162/A029

shape and dimensions of the deformed specimen, stresses and deformations forming in the test can be calculated. The calculation is based on approximation of the generatrix of the deformed specimen surface by a 4-th degree polynomial and the corresponding equivalent can be calculated by using the formula (21). The behavior of sheet steel can be investigated in a wide test speed range. Biaxial drawing in tests permits considerably higher deformations than uniaxial, and the accuracy of determination is higher. There is 1 photo and 8 references: 5 Soviet, 2 British, 1 Dutch.

TEXT: A new method of testing the deep-drawing properties of steel sheet has been developed at the metal-working laboratory of the Institut mashinovedeniya (Institute of Science of Machines). The method, based on the application of hydraulic impact created by a drop-hammer, is schematically demonstrated in Fig. 1, showing: 1 - anvil block; 2 - dynamometer; 3 - piston; 4 - cylinder; 5 - test piece; 6 - clamping nut; (when the piston 3 is made to hit the dynamometer 2 a pressure wave generated in the fluid contained in the cylinder deforms a circular test piece). In the present paper, concerned with the theory of the method, several formulas are derived, including formulas for the velocity  
Card 1/22

Theory of .....

5/002/02/000/010/015  
2105/2503

of the pressure wave, total pressure of the liquid in the cylinder and, finally, the total impact pressure  $P_m$  :

$$P_m = \frac{GH}{q} \quad (26)$$

where  $G$  is the weight of the falling parts of the drop-hammer,  $H$  the height of the drop,  $\eta$  the coefficient of the effective action of the impact and  $q$  the volume of liquid displaced by the impact. The stresses and strains during dynamic testing of steel sheet can be calculated from the calculated values of  $P_m$  and data on the shape and dimensions of the test piece. The equivalent velocity  $w$  can be found from the formula:

$$w = \sqrt{aCv} \quad (27)$$

where  $a$  is a coefficient taking into account the reflection of the impact wave,  $C$  is the wave velocity and  $v$  the impact velocity. There is 1 figure.

TITLE: Theory of plastic deformation of metals

PERIODICAL: Akademiya nauk SSSR. Vestnik, no. 5, 1962, 75-77

SYNOPSIS: This is a theoretical study of metal-working processes, some conventional and some new, which take advantage of the plasticity of metals. Plastic deformation resulting from pressure involves complex processes which can be explained by the theory of plasticity. In the case of actual metal-working processes, those problems in the theory of plasticity which as a rule are extremely difficult to solve mathematically can be simplified without rendering the solution inaccurate, if some parameters are either constant or functions of other parameters. In most cases solving the three-dimensional problem is reduced to solving the corresponding axially symmetrical problem (e.g., in wire drawing) or plane plasticity problem (e.g., in steel sheet rolling). An approximate solution of the spatial problem may be had if the stresses distributed over various cross sections of the deformable subject are considered as individual uniplanar problems.

# Theory of plastic deformation...

Theories based on ideal plasticity can be applied in studying the deformation of hot metals, since whatever solidification of metals takes place during the plastic flow is negligible at high temperatures. Deformation of cold metal by pressure can be calculated on the assumption of ideal plasticity or on that of plastic flow without solidification, since the solidification intensity decreases with increasing deformation. The parameter assumed here is the yield point of solidified metal. Cross-screw hot rolling has been introduced and successfully applied to machine construction in USSR during recent years. As regards productivity, this continuous method is far superior to hot punching. There are good prospects also for cold punching. The application of these methods is, however, restricted by extremely high specific pressures during the working process and by cracking of the material under high stresses. Theoretical studies of states of stress during cross-screw hot rolling made it possible to find out the causes for the formation of interior cracks and to develop preventive measures. The effect of friction still remains to be investigated and methods of controlling this phenomenon need to be developed. Pilot plants for the production of steel sections by hot-pressing are at present under construction. This method involves the solution of problems relating to the determination of state of stress and rate of flow in the inhomogeneous temperature field with varying

Card 2/3
